Facts & Figures:

Older Adults & Hearing Implants in the United States

Prevalence: Hearing Loss in Older Adults

There are more than 40 million Americans over the age of 65, representing 13% of the U.S. population. More people were 65 years and over in 2010 than in any previous census. Between 2000 and 2010, the population 65 years and over increased at a faster rate (15.1%) than the total U.S population (9.7%).

Almost 50 million Americans have hearing loss in at least one ear. Hearing loss becomes more prevalent with age: hearing impairment occurs in about 18% of American adults between ages 45 and 54, 30% of adults between ages 65 and 74, and 47% of adults ages 75 and older.

Hearing Implants and Older Adults

Despite the high prevalence of hearing loss and many treatment options available, only 10-20% of people with hearing loss have ever used hearing aids, and 20-29% of patients who have used hearing aids at some point stop using them. Patients often experience dissatisfaction with hearing aids due to their appearance, background noise, discomfort, difficulty handling, and unmet expectations regarding effects on hearing impairment.

When hearing loss progresses beyond the ability of hearing aids to produce meaningful benefit, a cochlear implant (CI) provides an alternative option by stimulating the auditory nerve and nervous system directly. Estimates indicate that approximately 150,000 adults over 70 in the United States likely have hearing loss of a severity that would meet cochlear implantation candidacy criteria. Research has shown that older adults who receive cochlear implants often successfully regain their lost sense of hearing.
Scientists have seen a great deal of success among older patients who receive cochlear implants, particularly those who are implanted earlier in their hearing loss experience.\(^6,7\) Scientists believe implantation of older adults earlier might promote better results because of relatively better neural plasticity, shorter duration of deafness, and less neural degeneration.

Older recipients have been shown to gain a substantial benefit from cochlear implants in terms of quality of life, as demonstrated by health status, success in the common activities of daily living and perceived satisfaction after cochlear implantation.\(^8,9\) Older adults who lost their hearing later in life obtained significant speech perception benefits from CIs, although differences in speech outcomes were seen between younger recipients and those implanted after age 70.\(^10\) Older adults have a similar learning curve to younger adults, and in speech tests in quiet they show a comparable performance. However, their performance is statistically significantly lower in noisy surroundings.\(^11\)

In addition to regaining the sense of hearing, there are many potential benefits of cochlear implants that are particularly relevant to older adults, such as maintaining independence, use of the telephone and participating in daily activities. Social reintegration and related emotional aspects of maintaining connections also benefit older CI patients.\(^12,13\) Older recipients with long-term deafness experience also a greater improvement in quality of life after implantation. Regardless of poorer audiologic outcomes compared to younger adults, the expected daily functional benefits of cochlear implantation are high.\(^14\)

Cochlear implantation is well tolerated across all adult age groups with a relatively low risk for adverse surgical events or device malfunction.\(^14\) Studies indicate that the safety profile of cochlear implantation in an older population is comparable to that of younger adults and children. Concerns for increased postoperative complications in recipients of advanced age do not need to be a primary consideration when determining CI candidacy.\(^16\) CI surgery for patients 79 years or older was well tolerated. Recipients benefited greatly from the device with improved hearing. CI should not be denied older individuals who are otherwise in good health.\(^17\)

Hearing Loss, Age and Cognitive Decline

In 2011, researchers from Johns Hopkins University published ground-breaking research definitively connecting hearing loss and cognitive decline in older adults. The NIH-funded study, led by Dr. Frank Lin, found that hearing loss was independently associated with dementia. The researchers also found that the risk for dementia increased exponentially with hearing loss severity. According to the researchers, these findings could lead to new ways to combat dementia, a condition that affects millions of people worldwide and carries heavy societal burdens.18,19

More recently, in 2013, Dr. Lin and his team published data showing that cognitive problems were appearing approximately 30-40% faster in older adults with mild hearing loss, as compared to their peers without hearing loss.20

Although the reason for the link between the two conditions is unknown, the investigators hypothesize that a common pathology may underlie both or that the strain of decoding sounds over the years may overwhelm the brains of people with hearing loss, leaving them more vulnerable to dementia. They also speculate that hearing loss could lead to dementia by making individuals more socially isolated, a known risk factor for dementia and other cognitive disorders.21,22 Although there are no data to support that hearing technology will mitigate dementia, researchers are seeking answers to this question.23
